

Biomes

Earth science

A **biome** is a large area of the Earth where certain plants and animals live. Biomes are determined largely by the area's climate.

Match each biome to its description.

aquatic

Receives very little rainfall, so wildlife here must adapt to store water.

grassland

Filled with dense trees and supports the greatest variety of plant and animal species.

desert

Gets enough rain for wild grasses to thrive, but too dry for large forests.

tundra

Made up of water environments, including both freshwater and ocean ecosystems.

forest

An extremely cold environment where the ground remains frozen throughout most of the year.

Choose one biome and describe its climate. Draw a picture showing some of the living things in the biome.
